Radiation Damping

S.A. Bogacz, G.A. Krafft, S. DeSilva and R. Gamage

Jefferson Lab and Old Dominion University
Outline

- Beam dynamics with synchrotron radiation:
  - Discuss the effect of synchrotron radiation on the (linear) motion of particles in storage rings.
  - Define action-angle variables for describing symplectic motion of a particle along a beam line.
  - Derive expressions for the damping times of the vertical, horizontal and longitudinal emittances.
  - Introduce the synchrotron radiation integrals (Sand’s Integrals).
  - Discuss the effects of quantum excitation, and derive expressions for the equilibrium horizontal and longitudinal beam emittances in an electron storage ring.

- M. Sands, “The physics of electron storage rings, an introduction” SLAC-121. 1970
- A. Wolski, University of Liverpool and the Cockcroft Institute, CAS 2009,
Coordinate system

\[ p_y = \frac{1}{P_0} \gamma m \frac{dy}{dt} \]

\[ p_x = \frac{1}{P_0} \gamma m \frac{dx}{dt} \]

\[ P_0 = \text{reference momentum} \]
The reference particle is a particle travelling along the reference trajectory with momentum $P_0$ and velocity $\beta_0 c$.

If a particle is time $\tau$ ahead of the reference particle, then the longitudinal coordinate $z$ is defined by:

$$z = c \tau$$
If the particle has total energy $E$, then the energy deviation $\delta$ is defined by:

$$\delta = \frac{E}{P_0 c} - \frac{1}{\beta_0}$$

For ultra-relativistic particles ($\beta \approx \beta_0 \approx 1$), we have:

$$\delta \approx \frac{\Delta E}{E_0}$$
Canonical variables

With the definitions in the previous slides, the coordinates and momenta form *canonical conjugate pairs*:

\[(x, p_x) \quad (y, p_y) \quad (z, \delta)\]

What this means, is that if $M$ represents the linear transfer matrix for a beam line consisting of some sequence of drifts, solenoids, dipoles, quadrupoles, or RF cavities, i.e.:

\[
\begin{pmatrix}
  x \\
  p_x \\
  y \\
  p_y \\
  z \\
  \delta
\end{pmatrix}_{s=s_1} = M(s_1; s_0)
\begin{pmatrix}
  x \\
  p_x \\
  y \\
  p_y \\
  z \\
  \delta
\end{pmatrix}_{s=s_0}
\]

then, neglecting radiation from the particle, the matrix $M$ is *symplectic*. 
Symplectic matrices

Mathematically, a matrix $M$ is symplectic if it satisfies the relation:

$$M^T U M = U$$

where $U$ is the antisymmetric matrix:

$$U = \begin{pmatrix}
0 & 1 & 0 & 0 & 0 & 0 \\
-1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & -1 & 0
\end{pmatrix}$$

Physically, symplectic matrices preserve areas in phase space.

For example, in one degree of freedom:
Twiss parameters and the particle action

In an *uncoupled* periodic beam line, particles trace out ellipses in phase space with each pass through the periodic cell. The shape of the ellipse defines the *Twiss parameters* at the observation point.

The area of the ellipse defines the *action* $J_x$ of the particle.

The action is the amplitude of the motion of the particle as it moves along the beam line.

Area of the ellipse $= 2\pi J_x$
Applying simple geometry to the phase space ellipse, we find that the action (for uncoupled motion) is related to the Cartesian variables for the particle by:

\[ 2J_x = \gamma x^2 + 2\alpha x p_x + \beta p_x^2 \]

We also define the angle \( \phi_x \) as follows:

\[ \tan \phi_x = -\beta x \frac{p_x}{x} - \alpha_x \]

The action-angle variables provide an alternative to Cartesian variables for describing the dynamics of a particle moving along a beam line. The advantage of action-angle variables is that, under symplectic transport, the action of a particle is constant.

It turns out that the action-angle variables are canonically conjugate.

Note: if the beam line is coupled, then we need to make a coordinate transformation to the "normal mode" coordinates, in which the motion in one mode is independent of the motion in the other modes. Then we can apply the equations as above.
Action and Emittance

The action $J_x$ is a variable used to describe the amplitude of the motion of an individual particle. In terms of the action-angle variables, the Cartesian coordinate and momentum can be written:

\[ x = \sqrt{2 \beta_x J_x} \cos \varphi_x \quad \quad p_x = -\sqrt{\frac{2J_x}{\beta_x}}(\sin \varphi_x + \alpha_x \cos \varphi_x) \]

The emittance $\varepsilon_x$ is the average amplitude of all particles in a bunch:

\[ \varepsilon_x = \langle J_x \rangle \]

With this relationship between the emittance and the average action, we can obtain the following familiar relationships for the second-order moments of the bunch:

\[ \langle x^2 \rangle = \beta_x \varepsilon_x \quad \quad \langle xp_x \rangle = -\alpha_x \varepsilon_x \quad \quad \langle p_x^2 \rangle = \gamma_x \varepsilon_x \]

Again, this is true for uncoupled motion.
So far, we have considered only symplectic transport, i.e. motion of a particle in the electromagnetic fields of drifts, dipoles, quadrupoles etc. without any radiation.

However, we know that a charged particle moving through an electromagnetic field will (in general) undergo acceleration, and a charged particle undergoing acceleration will radiate electromagnetic waves.

What impact will the radiation have on the motion of the particle?

In answering this question, we will consider first the case of uncoupled vertical motion – for a particle in a storage ring, this turns out to be the simplest case.
A relativistic particle will emit radiation with an opening angle of $1/\gamma$ with respect to its instantaneous direction of motion, where $\gamma$ is the relativistic factor.

For an ultra-relativistic particle, $\gamma \gg 1$, we can assume that the radiation is emitted directly along the instantaneous direction of motion of the particle.
Radiation damping of vertical emittance

The change in momentum of the particle is given by:

\[ p' = p - dp \approx p \left( 1 - \frac{dp}{P_0} \right) \]

where \( dp \) is the momentum carried by the radiation, and we assume that:

\[ p \approx P_0 \]

Since there is no change in direction of the particle, we must have:

\[ p'_y \approx p_y \left( 1 - \frac{dp}{P_0} \right) \]
Radiation damping of vertical emittance

After emission of radiation, the vertical momentum of the particle is:

\[ p'_y = p_y \left( 1 - \frac{dp}{P_0} \right) \]

Now we substitute this into the expression for the vertical betatron action (valid for \textit{uncoupled} motion):

\[ 2J_y = \gamma_y y^2 + 2\alpha_y y p_y + \beta_y p_y^2 \]

to find the change in the action resulting from the emission of radiation:

\[ dJ_y = -\left( \alpha_y y p_y + \beta_y p_y^2 \right) \frac{dp}{P_0} \]

We average over all particles in the beam, to find:

\[ \langle dJ_y \rangle = d\varepsilon_y = -\varepsilon_y \frac{dp}{P_0} \]

where we have used: \[ \langle yp_y \rangle = -\alpha_y \varepsilon_y \quad \langle p_y^2 \rangle = \gamma_y \varepsilon_y \quad \text{and} \quad \beta_y \gamma_y - \alpha_y^2 = 1 \]
Radiation damping of vertical emittance

For a particle moving round a storage ring, we can integrate the loss in momentum around the ring. The emittance is conserved under symplectic transport; so if the non-symplectic (radiation) effects are slow, we can write:

\[
d\varepsilon_y = -\varepsilon_y \frac{dp}{P_0} \quad \Rightarrow \quad \frac{d\varepsilon_y}{dt} = -\frac{\varepsilon_y}{T_0} \int \frac{dp}{P_0} \approx -\frac{U_0}{E_0 T_0} \varepsilon_y
\]

where \( T_0 \) is the revolution period, and \( U_0 \) is the energy loss in one turn. The approximation is valid for an ultra-relativistic particle, which has \( E \approx pc \).

We define the damping time \( \tau_y \):

\[
\tau_y = 2 \frac{E_0}{U_0} T_0
\]

so the evolution of the emittance is:

\[
\varepsilon_y(t) = \varepsilon_y(0) \exp \left( -2 \frac{t}{\tau_y} \right)
\]

Typically, the damping time in a synchrotron storage ring is measured in tens of milliseconds, whereas the revolution period is measured in microseconds; so the radiation effects really are "slow".
Radiation damping of vertical emittance

Note that we made the assumption that the momentum of the particle was close to the reference momentum:

\[ p \approx P_0 \]

If the particle continues to radiate without any restoration of energy, we will reach a point where this assumption is no longer valid. However, electron storage rings contain RF cavities to restore the energy lost by synchrotron radiation. But then, we have to consider the change in momentum of a particle as it moves through an RF cavity.

Fortunately, RF cavities are usually designed with a longitudinal electric field, so that particles experience a change in longitudinal momentum as they pass through, without any change in transverse momentum.
Synchrotron radiation energy loss

To complete our calculation of the vertical damping time, we need to find the energy lost by a particle through synchrotron radiation on each turn through the storage ring. We quote the (classical) result that the power radiated by a particle of charge $e$ and energy $E$ in a magnetic field $B$ is given by:

$$P_\gamma = \frac{C_\gamma}{2\pi} c^3 e^2 B^2 E^2$$

$C_\gamma$ is a constant, given by:

$$C_\gamma = \frac{e^2}{3\varepsilon_0 (mc^2)^4} \approx 8.846 \times 10^{-5} \text{ m/GeV}^3$$

A charged particle with energy $E$ in a magnetic field $B$ follows a circular trajectory with radius $\rho$, given by:

$$B\rho = \frac{E}{ec}$$

Hence the synchrotron radiation power can be written:

$$P_\gamma = \frac{C_\gamma}{2\pi} c \frac{E^4}{\rho^2}$$
Synchrotron radiation energy loss

For a particle with the nominal energy, and traveling at (close to) the speed of light around the closed orbit, we can find the energy loss simply by integrating the radiation power around the ring:

$$U_0 = \oint P_\gamma \, dt = \oint P_\gamma \, \frac{ds}{c}$$

Using the previous expression for $P_\gamma$, we find:

$$U_0 = \frac{C_\gamma}{2\pi} E_0^4 \oint \frac{1}{\rho^2} \, ds$$

Conventionally, we define the second synchrotron radiation integral, $I_2$:

$$I_2 = \oint \frac{1}{\rho^2} \, ds$$

In terms of $I_2$, the energy loss per turn $U_0$ is written:

$$U_0 = \frac{C_\gamma}{2\pi} E_0^4 I_2$$
The first synchrotron radiation integral

Note that $I_2$ is a property of the lattice (actually, of the reference trajectory), and does not depend on the properties of the beam.

Conventionally, there are five synchrotron radiation integrals defined, which are used to express in convenient form the dynamics of a beam emitting radiation.

The first synchrotron radiation integral is not, however, directly related to the radiation effects. It is defined as:

$$I_1 = \int \frac{\eta_x}{\rho} \, ds$$

where $\eta_x$ is the horizontal dispersion.

The momentum compaction factor, $\alpha_p$, can be written:

$$\alpha_p \equiv \frac{1}{C_0} \left. \frac{dC}{d\delta} \right|_{\delta=0} = \frac{1}{C_0} \int \frac{\eta_x}{\rho} \, ds = \frac{1}{C_0} I_1$$
Damping of horizontal emittance

Analysis of the radiation effects on the vertical emittance was relatively straightforward. When we consider the horizontal emittance, there are three complications that we need to address:

- The horizontal motion of a particle is often strongly coupled to the longitudinal motion.

- Where the reference trajectory is curved (usually, in dipoles), the path length taken by a particle depends on the horizontal coordinate with respect to the reference trajectory.

- Dipole magnets are sometimes built with a gradient, so that the vertical field seen by a particle in a dipole depends on the horizontal coordinate of the particle.
Horizontal-longitudinal coupling

Coupling between transverse and longitudinal planes in a beam line is usually represented by the dispersion, $\eta_x$. So, in terms of the horizontal dispersion, the horizontal coordinate and momentum of a particle are given by:

$$x = \sqrt{2\beta_x J_x} \cos \varphi_x + \eta_x \delta$$

$$p_x = -\sqrt{\frac{2J_x}{\beta_x}} (\sin \varphi_x + \alpha_x \cos \varphi_x) + \eta_{px} \delta$$

When a particle emits radiation, we have to take into account:

- the change in momentum of the particle (because of the momentum carried by the radiation);
- the change in coordinate $x$ and momentum $p_x$ resulting from the change in energy deviation $\delta$.

When we analysed the vertical motion, we ignored the second effect, because we assumed that the vertical dispersion was zero.
Damping of horizontal emittance

Taking all the above effects into account, we can proceed along the same lines as for the analysis of the vertical emittance. That is:

- Write down the changes in coordinate $x$ and momentum $p_x$ resulting from an emission of radiation with momentum $dp$ (taking into account the additional effects of dispersion).
- Substitute expressions for the new coordinate and momentum into the expression for the horizontal betatron action, to find the change in action resulting from the radiation emission.
- Average over all particles in the beam, to find the change in the emittance resulting from radiation emission from each particle.
- Integrate around the ring (taking account of changes in path length and field strength with $x$ in the bends) to find the change in emittance over one turn.

The algebra gets somewhat cumbersome, and is not especially enlightening: see Appendix A for more details. Here, we just quote the result...
Radiation damping of horizontal emittance

The horizontal emittance decays exponentially:

$$\frac{d\varepsilon_x}{dt} = -\frac{2}{\tau_x} \varepsilon_x$$

where the horizontal damping time is given by:

$$\tau_x = \frac{2 E_0}{j_x U_0 T_0}$$

The horizontal damping partition number $j_x$ is given by:

$$j_x = 1 - \frac{I_4}{I_2}$$

where the fourth synchrotron radiation integral $I_4$ is given by:

$$I_4 = \frac{n_x}{\rho} \left( \frac{1}{\rho^2 + 2k_1} \right) ds$$

$$k_1 = \frac{e}{P_0} \frac{\partial B_y}{\partial x}$$
Appendix A: Damping of horizontal emittance

In this Appendix, we derive the expression for radiation damping of the horizontal emittance:

\[
\frac{d\xi_x}{dt} = -\frac{2}{\tau_x} \xi_x
\]

where:

\[
\tau_x = \frac{2}{j_x} \frac{E_0}{U_0} T_0 \quad j_x = 1 - \frac{I_4}{I_2}
\]

To do this, we proceed as follows:

1. We find an expression for the change of horizontal action of a single particle when emitting radiation with momentum \( dp \).
2. We integrate around the ring to find the change in action per revolution period.
3. We average the action over all particles in the bunch, to find the change in emittance per revolution period.
Appendix A: Damping of horizontal emittance

To begin, we note that, in the presence of dispersion, the action $J_x$ is written:

$$2J_x = \gamma_x \tilde{x}^2 + 2\alpha_x \tilde{x} \tilde{p}_x + \beta_x \tilde{p}_x^2$$

where:

$$\tilde{x} = x - \eta_x \delta, \quad \tilde{p}_x = p_x - \eta_{px} \delta$$

After emission of radiation carrying momentum $dp$, the variables change by:

$$\delta \mapsto \delta - \frac{dp}{P_0}, \quad \tilde{x} \mapsto \tilde{x} + \frac{\eta_x}{P_0} dp, \quad \tilde{p}_x \mapsto \tilde{p}_x \left(1 - \frac{dp}{P_0}\right) + \eta_{px} (1 - \delta) \frac{dp}{P_0}$$

The resulting change in the action is:

$$J_x \mapsto J_x + dJ_x$$
Appendix A: Damping of horizontal emittance

The change in the horizontal action is:

\[ dJ_x = -w_1 \frac{dp}{P_0} + w_2 \left( \frac{dp}{P_0} \right)^2 \]

\[ \therefore \quad \frac{dJ_x}{dt} = -w_1 \frac{1}{P_0} \frac{dp}{dt} + w_2 \frac{dp}{P_0^2} \frac{dp}{dt} \quad \text{(A1)} \]

where, in the limit \( \delta \to 0 \):

\[ w_1 = \alpha_x p_x + \beta_x p_x^2 - \eta_x (\gamma_x p_x + \alpha_x p_x) - \eta_{px} (\alpha_x p_x + \beta_x p_x) \quad \text{(A2)} \]

and:

\[ w_2 = \frac{1}{2} (\gamma_x \eta_x^2 + 2 \alpha_x \eta_x \eta_{px} + \beta_x \eta_{px}^2) - (\alpha_x \eta_x + \beta_x \eta_{px}) p_x + \frac{1}{2} \beta_x p_x^2 \quad \text{(A3)} \]

Treating radiation as a classical phenomenon, we can take the limit \( dp \to 0 \) in the limit of small time interval, \( dt \to 0 \). In this approximation:

\[ \frac{dJ_x}{dt} \approx -w_1 \frac{1}{P_0} \frac{dp}{dt} \approx -w_1 \frac{P_\gamma}{P_0 c} \]

where \( P_\gamma \) is the rate of energy loss of the particle through radiation.
Appendix A: Damping of horizontal emittance

To find the \textit{average} rate of change of horizontal action, we integrate over one revolution period:

\[
\frac{dJ_x}{dt} = -\frac{1}{T_0} \int w_1 \frac{P_\gamma}{P_0 c} \, dt
\]

We have to be careful changing the variable of integration where the reference trajectory is curved:

\[
dt = \frac{dC}{c} = \left(1 + \frac{x}{\rho}\right) \frac{ds}{c}
\]

So:

\[
\frac{dJ_x}{dt} = -\frac{1}{T_0 P_0 c^2} \int w_1 P_\gamma \left(1 + \frac{x}{\rho}\right) \, ds \tag{A4}
\]

where the rate of energy loss is:

\[
P_\gamma = \frac{C_\gamma}{2\pi} c^3 e^2 B^2 E^2 \tag{A5}
\]
Appendix A: Damping of horizontal emittance

We have to take into account the fact that the field strength in a dipole can vary with position. To first order in $x$ we can write:

$$B = B_0 + x \frac{\partial B_y}{\partial x} \quad (A6)$$

Substituting equation (A6) into (A5), and with the use of (A2), we find (after some algebra!) that, averaging over all particles in the beam:

$$\int \left( w_1 p_y \left( 1 + \frac{x}{\rho} \right) \right) ds = c U_0 \left( 1 - \frac{I_4}{I_2} \right) \varepsilon_x \quad (A7)$$

where:

$$U_0 = \frac{C_y}{2\pi} c E_0 I_2 \quad I_2 = \int \frac{1}{\rho^2} ds \quad I_4 = \int \frac{\eta_x}{\rho} \left( \frac{1}{\rho^2} + 2k_1 \right) ds$$

and $k_1$ is the quadrupole gradient in the dipole field:

$$k_1 = \frac{e}{P_0} \frac{\partial B_y}{\partial x}$$
Appendix A: Damping of horizontal emittance

Combining equations (A4) and (A7) we have:

\[
\frac{d\varepsilon_x}{dt} = -\frac{1}{T_0} \frac{U_0}{E_0} \left(1 - \frac{I_4}{I_2}\right) \varepsilon_x
\]

Defining the horizontal damping time, \(\tau_x\):

\[
\tau_x = \frac{2}{j_x} \frac{E_0}{U_0} T_0 \quad j_x = 1 - \frac{I_4}{I_2}
\]

the evolution of the horizontal emittance can be written:

\[
\frac{d\varepsilon_x}{dt} = -\frac{2}{\tau_x} \varepsilon_x
\]

The quantity \(j_x\) is called the horizontal damping partition number. For most lattices, if there is no gradient in the dipoles, then \(j_x\) is very close to 1.
Damping of synchrotron oscillations

So far, we have considered the effects of synchrotron radiation on the transverse motion. There are also effects on the longitudinal motion.

Generally, synchrotron oscillations are handled differently from betatron oscillations, because the synchrotron tune in a storage ring is usually much less than 1, whereas the betatron tunes are much greater than 1.

To find the effects of radiation on synchrotron motion, we proceed as follows:

- We write down the equations of motion (for the variables $z$ and $\delta$) for a particle performing synchrotron motion, including the radiation energy loss.
- We express the energy loss per turn as a function of the energy deviation of the particle. This introduces a "damping term" into the equations of motion.
- Solving the equations of motion gives synchrotron oscillations (as expected) with amplitude that decays exponentially.
Damping of synchrotron oscillations

The change in energy deviation $\delta$ and longitudinal coordinate $z$ for a particle in one turn around a storage ring are given by:

$$\Delta \delta = \frac{eV_{RF}}{E_0} \sin \left( \varphi_s - \frac{\omega_{RF} z}{c} \right) - \frac{U}{E_0}$$

$$\Delta z = -\alpha_p C_0 \delta$$

where $V_{RF}$ is the RF voltage and $\omega_{RF}$ the RF frequency, $E_0$ is the reference energy of the beam, $\varphi_s$ is the nominal RF phase, and $U$ is the energy lost by the particle through synchrotron radiation.

If the revolution period is $T_0$, then we can write the longitudinal equations of motion for the particle:

$$\frac{d\delta}{dt} = \frac{eV_{RF}}{E_0 T_0} \sin \left( \varphi_s - \frac{\omega_{RF} z}{c} \right) - \frac{U}{E_0 T_0}$$

$$\frac{dz}{dt} = -\alpha_p c \delta$$
Damping of synchrotron oscillations

Let us assume that \( z \) is small compared to the RF wavelength, i.e. \( \omega_{RF}z/c << 1 \).

Also, the energy loss per turn is a function of the energy of the particle (particles with higher energy radiate higher synchrotron radiation power), so we can write (to first order in the energy deviation):

\[
U = U_0 + \Delta E \frac{dU}{dE} \bigg|_{E=E_0} = U_0 + E_0 \delta \frac{dU}{dE} \bigg|_{E=E_0}
\]

Further, we assume that the RF phase \( \varphi_s \) is set so that for \( z = \delta = 0 \), the RF cavity restores exactly the amount of energy lost by synchrotron radiation. The equations of motion then become:

\[
\frac{d\delta}{dt} = -\frac{eV_{RF}}{E_0 T_0} \cos \varphi_s \frac{\omega_{RF}}{c} z - \frac{1}{T_0} \delta \frac{dU}{dE} \bigg|_{E=E_0}
\]

\[
\frac{dz}{dt} = -\alpha_p c \delta
\]
Combining these equations gives:

\[ \frac{d^2 \delta}{dt^2} + 2\alpha_E \frac{d\delta}{dt} + \omega_s^2 \delta = 0 \]

This is the equation for a damped harmonic oscillator, with frequency \( \omega_s \) and damping constant \( \alpha_E \) given by:

\[ \omega_s^2 = -\frac{eV_{RF}}{E_0} \cos \varphi_s \frac{\omega_{RF}}{T_0} \alpha_p \]

\[ \alpha_E = \frac{1}{2T_0} \left. \frac{dU}{dE} \right|_{E=E_0} \]
Damping of synchrotron oscillations

If $\alpha_E << \omega_s$, the energy deviation and longitudinal coordinate damp as:

$$\delta(t) = \hat{\delta} \exp(-\alpha_E t) \sin(\omega_s t - \theta_0)$$

$$z(t) = \frac{\alpha_p c}{\omega_s} \hat{\delta} \exp(-\alpha_E t) \cos(\omega_s t - \theta_0)$$

To find the damping constant $\alpha_E$, we need to know how the energy loss per turn $U$ depends on the energy deviation $\delta$...
Damping of synchrotron oscillations

We can find the total energy lost by integrating over one revolution period:

\[ U = \int P_r \, dt \]

To convert this to an integral over the circumference, we should recall that the path length depends on the energy deviation; so a particle with a higher energy takes longer to travel round the lattice.

\[ dt = \frac{dC}{c} \]

\[ dC = \left(1 + \frac{x}{\rho}\right) ds = \left(1 + \frac{\eta \delta}{\rho}\right) ds \]

\[ U = \frac{1}{c} \int P_r \left(1 + \frac{\eta \delta}{\rho}\right) ds \]
Damping of synchrotron oscillations

With the energy loss per turn given by:

\[ U = \frac{1}{c} \oint P_y \left( 1 + \frac{\eta_x}{\rho} \delta \right) ds \]

and the synchrotron radiation power given by:

\[ P_y = \frac{C_y}{2\pi} c^3 e^2 B^2 E^2 = \frac{C_y}{2\pi} c \frac{E^4}{\rho^2} \]

we find, after some algebra:

\[ \left. \frac{dU}{dE} \right|_{E=E_0} = j_E \frac{U_0}{E_0} \]

where:

\[ U_0 = \frac{C_y}{2\pi} E_0^4 I_2 \]

\[ j_E = 2 + \frac{I_4}{I_2} \]

\[ I_2 = \oint \frac{1}{\rho^2} ds \]

\[ I_4 = \oint \eta_x \rho \left( \frac{1}{\rho^2} + 2k_1 \right) ds \]

\[ k_1 = \frac{e}{P_0} \frac{\partial B_y}{\partial x} \]
Finally, we can write the longitudinal damping time:

$$\tau_z = \frac{1}{\alpha_E} = \frac{2}{j_z} \frac{E_0}{U_0} T_0$$

$U_0$ is the energy loss per turn for a particle with the reference energy $E_0$, following the reference trajectory. It is given by:

$$U_0 = \frac{C}{2\pi} E_0^4 I_2$$

$j_z$ is the longitudinal damping partition number, given by:

$$j_z = 2 + \frac{I_4}{I_2}$$
The longitudinal emittance is given by a similar expression to the horizontal and vertical emittances:

$$\varepsilon_z = \sqrt{\langle z^2 \rangle \langle \delta^2 \rangle - \langle z\delta \rangle^2}$$

In most storage rings, the correlation \( \langle z\delta \rangle \) is negligible, so the emittance becomes:

$$\varepsilon_z \approx \sigma_z \sigma_\delta$$

Hence, the damping of the longitudinal emittance can be written:

$$\varepsilon_z(t) = \varepsilon_z(0) \exp\left(-2 \frac{t}{\tau_z}\right)$$
Summary: synchrotron radiation damping

The energy loss per turn is given by:

\[ U_0 = \frac{C_\gamma}{2\pi} E_0^4 I_2 \]

\[ C_\gamma = 8.846 \times 10^{-5} \text{ m/GeV}^3 \]

The radiation damping times are given by:

\[ \tau_x = \frac{2}{j_x} \frac{E_0}{U_0} T_0 \]
\[ \tau_y = \frac{2}{j_y} \frac{E_0}{U_0} T_0 \]
\[ \tau_z = \frac{2}{j_z} \frac{E_0}{U_0} T_0 \]

The damping partition numbers are:

\[ j_x = 1 - \frac{I_4}{I_2} \]
\[ j_y = 1 \]
\[ j_z = 2 + \frac{I_4}{I_2} \]

The second and fourth synchrotron radiation integrals are:

\[ I_2 = \int \frac{1}{\rho^2} ds \]
\[ I_4 = \int \frac{\eta_x}{\rho} \left( \frac{1}{\rho^2 + 2k_1} \right) ds \]
Quantum excitation

If radiation were a purely classical process, the emittances would damp to nearly zero. However radiation is emitted in discrete units (photons), which induces some “noise” on the beam. The effect of the noise is to increase the emittance. The beam eventually reaches an equilibrium determined by a balance between the radiation damping and the quantum excitation.
Quantum excitation of horizontal emittance

By considering the change in the phase-space variables when a particle emits radiation carrying momentum $dp$, we find that the associated change in the betatron action is:

$$dJ_x = -w_1 \frac{dp}{P_0} + w_2 \left( \frac{dp}{P_0} \right)^2$$

where $w_1$ and $w_2$ are functions of the Twiss parameters, the dispersion, and the phase-space variables (see Appendix A).

The time evolution of the action can then be written:

$$\frac{dJ_x}{dt} = -w_1 \frac{1}{P_0} \frac{dp}{dt} + w_2 \frac{dp}{P_0^2} \frac{dp}{dt}$$

In the classical approximation, we can take $dp \to 0$ in the limit of small time interval, $dt \to 0$. In this approximation, the second term on the right hand side in the above equation vanishes, and we are left only with damping. But since radiation is quantized, it makes no real sense to take $dp \to 0$…
Quantum excitation of horizontal emittance

To take account of the quantization of synchrotron radiation, we write the time-evolution of the action as:

\[
\frac{dJ_x}{dt} = -w_1 \frac{1}{P_0} \frac{dp}{dt} + \frac{w_2}{P_0^2} \frac{dp}{dt} \quad \therefore \quad \frac{dJ_x}{dt} = -w_1 \dot{N} \frac{\langle u \rangle}{P_0 c} + w_2 \dot{N} \frac{\langle u^2 \rangle}{P_0^2 c^2}
\]

where \( u \) is the photon energy, and \( \dot{N} \) is the number of photons emitted per unit time.

In Appendix B, we show that this leads to the equation for the evolution of the emittance, including both radiation damping and quantum excitation:

\[
\frac{d\varepsilon_x}{dt} = -\frac{2}{\tau_x} \varepsilon_x + \frac{2}{j_x \tau_x} C_q \gamma^2 \frac{I_5}{I_2}
\]

where the fifth synchrotron radiation integral \( I_5 \) is given by:

\[
I_5 = \int \frac{f_{Hx}}{\rho^3} \, ds
\]

and the "quantum constant" \( C_q \) is given by:

\[
C_q = \frac{55}{32\sqrt{3}} \frac{\hbar}{mc} \approx 3.832 \times 10^{-13} \text{ m}
\]
Appendix B: Quantum excitation of horizontal emittance

In deriving the equation of motion (A4) for the action of a particle emitting synchrotron radiation, we made the classical approximation that in a time interval $dt$, the momentum of the radiation emitted $dp$ goes to zero as $dt$ goes to zero.

In reality, emission of radiation is quantized, so writing "$dp \to 0$" actually makes no sense.

Taking into account the quantization of radiation, the equation of motion for the action (A1) should be written:

$$dJ_x = -w_1 \frac{dp}{P_0} + w_2 \left( \frac{dp}{P_0} \right)^2 \quad \therefore \quad \frac{dJ_x}{dt} = -w_1 \dot{N} \frac{\langle u \rangle}{P_0 c} + w_2 \dot{N} \frac{\langle u^2 \rangle}{P_0^2 c^2} \quad (B1)$$

where $\dot{N}$ is the number of photons emitted per unit time.

The first term on the right hand side of (B1) just gives the same radiation damping as in the classical approximation. The second term on the right hand side of (B1) is an excitation term that we previously neglected...
Appendix B: Quantum excitation of horizontal emittance

Averaging around the circumference of the ring, the quantum excitation term can be written:

\[ w_2 N \frac{\langle u^2 \rangle}{P_0^2 c^2} \approx \frac{1}{C_0} \oint w_2 N \frac{\langle u^2 \rangle}{P_0^2 c^2} \, ds \]

Using equation (A3) for \( w_2 \), we find that (for \( x \ll \eta_x \) and \( p_x \ll \eta_{px} \)) the excitation term can be written:

\[ w_2 N \frac{\langle u^2 \rangle}{P_0^2 c^2} \approx \frac{1}{2E_0^2 C_0} \oint \mathcal{H}_x N \langle u^2 \rangle \, ds \]

where the "curly-H" function \( \mathcal{H}_x \) is given by:

\[ \mathcal{H}_x = \gamma_x \eta_x^2 + 2\alpha_x \eta_x \eta_{px} + \beta_x \eta_{px}^2 \]
Appendix B: Quantum excitation of horizontal emittance

Including both (classical) damping and (quantum) excitation terms, and averaging over all particles in the bunch, we find that the horizontal emittance evolves as:

\[
\frac{d\varepsilon_x}{dt} = -\frac{2}{\tau_x} \varepsilon_x + \frac{1}{2E_0^2C_0} \int \dot{\mathcal{N}} \langle u^2 \rangle \mathcal{H}_x \, ds
\]  \hspace{1cm} (B2)

We quote the result (from quantum radiation theory):

\[
\dot{\mathcal{N}} \langle u^2 \rangle = 2C_\gamma \gamma^2 E_0 \frac{P_\gamma}{\rho}
\]  \hspace{1cm} (B3)

where the “quantum constant” \( C_\gamma \) is:

\[
C_\gamma = \frac{55}{32\sqrt{3}} \frac{\hbar}{mc} \approx 3.832 \times 10^{-13} \text{ m}
\]
Appendix B: Quantum excitation of horizontal emittance

Using equation (B3), and equation (A5) for $P_y$, and the results:

$$j_x \tau_x = 2 \frac{E_0}{U_0} T_0 \quad \text{and} \quad U_0 = \frac{C_y}{2\pi} cE_0^4 I_2$$

we find that equation (B2) for the evolution of the emittance can be written:

$$\frac{d\varepsilon_x}{dt} = -\frac{2}{\tau_x} \varepsilon_x + \frac{2}{j_x \tau_x} C_q \gamma^2 \frac{I_5}{I_2}$$

where the fifth synchrotron radiation integral $I_5$ is given by:

$$I_5 = \int \frac{\mathcal{H}_x}{|\rho|^3} \, ds$$

Note that the excitation term is independent of the emittance: it does not simply modify the damping time, but leads to a non-zero equilibrium emittance.
Quantum excitation of horizontal emittance

The equilibrium horizontal emittance is found from:

\[ \frac{d\varepsilon_x}{dt}\bigg|_{\varepsilon_x=\varepsilon_0} = 0 \quad \therefore \quad \frac{2}{\tau_x} \varepsilon_0 = \frac{2}{j_x\tau_x} C_q \gamma^2 \frac{I_5}{I_2} \]

The equilibrium horizontal emittance is given by:

\[ \varepsilon_0 = C_q \gamma^2 \frac{I_5}{j_x I_2} \]

Note that \( \varepsilon_0 \) is determined by the beam energy, the lattice functions (Twiss parameters and dispersion) in the dipoles, and the bending radius in the dipoles.

\( \varepsilon_0 \) is sometimes called the “natural emittance” of the lattice, since it is the horizontal emittance that will be achieved in the limit of zero bunch charge: as the current is increased, interactions between particles in a bunch can increase the emittance above the equilibrium determined by radiation effects.
Quantum excitation of vertical emittance

In many storage rings, the vertical dispersion in the absence of alignment, steering and coupling errors is zero, so $\mathcal{H}_y = 0$. However, the equilibrium vertical emittance is larger than zero, because the vertical opening angle of the radiation excites some vertical betatron oscillations.

The fundamental lower limit on the vertical emittance, from the opening angle of the synchrotron radiation, is given by\(^{(1)}\):

$$
\varepsilon_y = \frac{13}{55} \frac{C_q}{I_2} \oint \frac{\beta_y}{\rho^3} \, ds
$$

In most storage rings, this is an extremely small value, typically four orders of magnitude smaller than the natural (horizontal) emittance.

In practice, the vertical emittance is dominated by magnet alignment errors. Storage rings typically operate with a vertical emittance that is of order 1% of the horizontal emittance, but many can achieve emittance ratios somewhat smaller than this.

Quantum effects excite longitudinal emittance as well as transverse emittance. Consider a particle with longitudinal coordinate $z$ and energy deviation $\delta$, which emits a photon of energy $\nu$.

\[
\delta' = \hat{\delta}' \sin \theta' = \hat{\delta} \sin \theta - \frac{\nu}{E_0}
\]

\[
z' = \frac{\alpha_p c}{\omega_s} \hat{\delta} \cos \theta' = \frac{\alpha_p c}{\omega_s} \hat{\delta} \cos \theta
\]

\[
\therefore \Delta^2 = \hat{\delta}^2 - 2 \hat{\delta} \frac{\nu}{E_0} \sin \theta + \frac{\nu^2}{E_0^2}
\]

Averaging over the bunch gives:

\[
\Delta \sigma^2_\delta = \frac{\langle \nu^2 \rangle}{2E_0^2} \quad \text{where} \quad \sigma^2_\delta = \frac{1}{2} \langle \hat{\delta}^2 \rangle
\]
Quantum excitation of synchrotron oscillations

Including the effects of radiation damping, the evolution of the energy spread is:

\[
\frac{d\sigma_\delta^2}{dt} = \frac{1}{2E_0 C_0} \oint \dot{N}\langle u^2 \rangle \, ds - \frac{2}{\tau_z} \sigma_\delta^2
\]

Using equation (B3) from Appendix B for \(\dot{N}\langle u^2 \rangle\), we find:

\[
\frac{d\sigma_\delta^2}{dt} = C_q \gamma^2 \frac{2}{j_z \tau_z} \frac{I_3}{I_2} - \frac{2}{\tau_z} \sigma_\delta^2
\]

We find the equilibrium energy spread from \(d\sigma_\delta^2/dt = 0\):

\[
\sigma_{\delta 0}^2 = C_q \gamma^2 \frac{I_3}{j_z I_2}
\]

The third synchrotron radiation integral \(I_3\) is given by:

\[
I_3 = \oint \frac{1}{|\rho^3|} \, ds
\]
Natural energy spread

The equilibrium energy spread determined by radiation effects is:

\[ \sigma_{\delta 0}^2 = C_q \gamma^2 \frac{I_3}{j_z I_2} \]

This is often referred to as the “natural” energy spread, since collective effects can often lead to an increase in the energy spread with increasing bunch charge.

The natural energy spread is determined essentially by the beam energy and by the bending radii of the dipoles. Note that the natural energy spread does not depend on the RF parameters (either voltage or frequency).

The corresponding equilibrium bunch length is:

\[ \sigma_z = \frac{\alpha_p c}{\omega_s} \sigma_\delta \]

We can increase the synchrotron frequency \( \omega_s \), and hence reduce the bunch length, by increasing the RF voltage, or by increasing the RF frequency.
Summary: Radiation Damping

Including the effects of radiation damping and quantum excitation, the emittances vary as:

\[ \varepsilon(t) = \varepsilon(0) \exp\left(-\frac{2t}{\tau}\right) + \varepsilon(\infty) \left[ 1 - \exp\left(-\frac{2t}{\tau}\right) \right] \]

The damping times are given by:

\[ j_x \tau_x = j_y \tau_y = j_z \tau_z = 2 \frac{E_0}{U_0} T_0 \]

The damping partition numbers are given by:

\[ j_x = 1 - \frac{I_4}{I_2} \quad j_y = 1 \quad j_z = 2 + \frac{I_4}{I_2} \]

The energy loss per turn is given by:

\[ U_0 = \frac{C_y}{2\pi} \frac{E_0^4 I_2}{I_2} \quad C_y = 8.846 \times 10^{-5} \text{ m/GeV}^3 \]
The natural emittance is:

\[ \varepsilon_0 = C_q \gamma^2 \frac{I_5}{j_x I_2} \quad C_q = 3.832 \times 10^{-13} \text{ m} \]

The natural energy spread and bunch length are given by:

\[ \sigma^2_\delta = C_q \gamma^2 \frac{I_3}{j_z I_2} \quad \sigma_z = \frac{\alpha_p c}{\omega_s} \sigma_\delta \]

The momentum compaction factor is:

\[ \alpha_p = \frac{I_1}{C_0} \]

The synchrotron frequency and synchronous phase are given by:

\[ \omega_s^2 = -\frac{eV_{RF}}{E_0} \frac{\omega_{RF}}{T_0} \alpha_p \cos \varphi_s \quad \sin \varphi_s = \frac{U_0}{eV_{RF}} \]
Summary: Sand’s Integrals

The synchrotron radiation integrals are:

\[ I_1 = \oint \frac{\eta_x}{\rho} \, ds \]
\[ I_2 = \oint \frac{1}{\rho^2} \, ds \]
\[ I_3 = \oint \frac{1}{|\rho|^3} \, ds \]
\[ I_4 = \oint \frac{\eta_x}{\rho} \left( \frac{1}{\rho^2} + 2k_1 \right) \, ds \quad k_1 = \frac{e}{P_0} \frac{\partial B_y}{\partial x} \]
\[ I_5 = \oint \frac{\mathcal{H}_x}{|\rho|^3} \, ds \quad \mathcal{H}_x = \gamma_x \eta_x^2 + 2\alpha_x \eta_x \eta_{px} + \beta_x \eta_{px}^2 \]
Summary

So far we have:

- discussed the effect of synchrotron radiation on the (linear) motion of particles in storage rings;

- derived expressions for the damping times of the vertical, horizontal and longitudinal emittances;

- discussed the effects of quantum excitation, and derive expressions for the equilibrium horizontal and longitudinal beam emittances in an electron storage ring.
